Abstract

A new undergraduate computer engineering curriculum, ICED, is being introduced at the University of Rhode Island. The main feature of the curriculum is a design project spanning the last three years of the major. This gives continuity to a student's studies: they will always know why they are learning a particular topic, and how it fits into the big picture. It also introduces them to long-term projects, and the requisite good documentation and communication habits necessary for its completion.

The project to be undertaken is the design, simulation and construction of a computer and its compiler, including the design of its instruction set. Further, the various students' computers will be networked together during the final integration phase of the project. Thus, several aspects of computer architecture are treated in depth. Students will learn to make hardware/software design tradeoffs, as well as get hands-on experience with hardware.

A key element of the design experience is the use of modern CAD tools. The Mentor Graphics CAD tool suite will be used throughout the curriculum. By standardizing on one set of tools, the time for the students to learn the tools is amortized over the entire curriculum.

The curriculum has received funding from the National Science Foundation, and has been formally approved by the University. Students began the curriculum in Fall, 1997.

This paper gives the rationale of ICED in depth, and describes the core courses, their activities and use of CAD tools, and how they interrelate to achieve the goals. The current status of ICED is also reviewed.

1 Introduction

The University of Rhode Island has developed a novel undergraduate Computer Engineering (CE) major curriculum. Traditional CE curricula are composed of disparate courses which poorly unify key themes and do not allow students to develop critical abilities. The Electrical and Computer Engineering (ELE) department at URI will remedy these ills with a new CE curriculum. The centerpiece of the curriculum will be the design of a richly complex digital system: a network of computers including, particularly, a computer with hardware and important system software built entirely by each student. This project will span the courses taken for the last 3 years of each undergraduate's studies.

This curriculum will allow a novel emphasis on fundamental engineering understanding, which can not be developed in projects of shorter duration. Students will develop an understanding of how design decisions play out over time, they will employ sophisticated design techniques using standard simulation and synthesis tools and they will make complex software/hardware tradeoffs.

This unified, longitudinal Integrated Computer Engineering Design (ICED) curriculum has been planned over several years. It has been accepted by the university.

This paper introduces the ICED curriculum and provides a broad view of the key use of CAD tools in ICED. The status of the program is also given.

This work was supported in part by the National Science Foundation through grant number DUE-9751215, and in part with software donations from Mentor Graphics Corp., Virtual Computer Corp., and Xilinx Corp. Earlier versions of this paper appeared at the 1997 Mentor Users' Group Conference, and at WCAE-4 at the 1998 HPCA conference.

Curricular Need - The old version of the computer engineering curriculum lacked cohesion, as well as large-systems design, construction and evaluation. Also, there was not a large software component, and hardware and software were not linked in a meaningful way, especially to understand the tradeoffs between the two. Further, the emphasis on networks was not as great as it should be, especially considering the explosive growth of the Internet.

The students need experience in complex digital system design, simulation, construction and evaluation. Although design these days is predominantly done with simulation, physical experience with complex hardware is essential for a computer engineer. "...there is something about late night debugging of that 'last' hardware problem that gives student engineers respect for the real difficulties of hardware, that simulations alone do not provide."[1]

Related Curricula - Several schools design and build computers as part of their CE curricula, e.g., Georgia Tech[3, 4], UCSC[11] and others[5]. However, such projects are usually done all at once, as capstone Senior design projects. A key element of ICED is a three-year long in-depth design project as part of most of the CE courses.

Some schools also involve compilers in the capstone projects. At Georgia Tech, this includes the modification of a retargetable C compiler to accommodate the student-designed computer. However, compiler construction in general is not incorporated in the experience; to our knowledge no school integrates a complete compiler design course with the computer hardware component of a CE curriculum. In fact, no school seems to require a compiler construction course as part of its CE curriculum[5]. Therefore, in such traditional curricula, the opportunity to make hardware/software design tradeoffs is relatively restricted, especially considering the large role such issues have in current computer (and most digital system) design. ICED requires a compiler construction course; it is integrated with the major project.

Many excellent tools have been devised to study computer architecture[6]. While they may provide much in the realm of understanding of an existing architecture, they do not give the student much freedom in design, hardware/software tradeoffs are not investigated in detail, and the student does not work on real hardware, only simulations. In [13], a comprehensive simulation environment employing both varying software and hardware components is available to the student; however, the student is only able to change system specifications: the changes to the compiler and hardware are made automatically. This does not give the student any design experience, and forces the student to only use the options allowed by the simulator writers. In our initial experience with allowing the student almost complete freedom in architectural specification and design, we have been amazed at the rich diversity of approaches students have taken in their designs, a refreshing change from the usual vanilla 32-bit RISC CPU.

Another issue involves the design tools used in a curriculum. Although it is possible to construct one's own in-house CAD (Computer-Aided-Design) tools[1], keeping them simple (as compared to industrial tools) and thus easier to learn, the student then does not experience the full power of industrial tools, nor does she/he become acclimated to the complexities of real-world design. Another issue is that at some schools different design tools are used in different courses, adding to the overhead of tool-learning time to the student. In ICED, the industrial CAD tool suite from Mentor Graphics will be used throughout the curriculum.

In current curricula, students do not participate in projects lasting more than one or two semesters. In practice, projects last much longer, often years. With the major project occurring over three years, ICED necessitates that the student create clear documentation, and deal with outcomes beyond any one course.

There are related projects. In [7] and others, networks and distributed systems are investigated, but only from a programming point of view, and the studies are not integrated with other topics. Integrated research across the curriculum is proposed in [12], but this is in the field of Psychology.

[1] Robert Colwell, Chief Architect of the Intel Pentium Pro, at the panel session at the International Symposium on Computer Architecture, May, 1996 (paraphrased).

In a closer but still different area, [9] proposes an integrated curriculum in Digital Signal Processing and Communications. Many hardware simulation, design, and emulation or construction curriculum projects have been pursued, including the use of modern Field Programmable Gate Array chips, such as in [2, 8], but the study of compilers was not included, networks were not addressed, and the work was not integrated across a curriculum.

2 The New CE Curriculum

A key ingredient to successful digital system design is making appropriate design tradeoffs amongst the hardware and software components of the system to achieve a suitably-performing, cost-effective design. The ICED curriculum ties together what is traditionally unrelated content from different courses. This allows students a key, novel experience – the design, over years of study, of an actual, complete, working network, particularly including a computer with both the processor and the compiler built by the student.

The design tasks to achieve these aims are distributed amongst the required core courses as follows. The courses are taken roughly in the order shown. The catalog descriptions of the courses are given first, then the design tasks are described in *[italics]*, followed by the names of tools used (all of them Mentor, unless noted otherwise).

1. **ELE 201/202 - Digital Circuit Design:** Logic gates, Boolean algebra, combinational and sequential circuits, analysis and design of sequential systems, multi-input system controllers, asynchronous finite state machines. Laboratory experience in digital electronics; logic design projects using standard integrated circuits.

   [Familiarization with industry-standard CAD tools. Design, simulation, construction and test of components for the computer, e.g., an adder, as well as simple control circuits. Introduction to the VHDL hardware modeling language.] Design Architect (schematic capture), Quicksim II (schematic simulation), QuickHDL (VHDL Compilation and Simulation).

2. **ELE 305 - Introduction to Computer Architecture:** Architecture of digital computers. CPU microarchitecture. Instruction execution cycle. Instruction sets. The memory hierarchy. Pipelining, instruction level parallelism, introduction to parallel computing. Register-level design and simulation of a simple computer.

   [Design and simulation of a simple machine instruction set for the student's computer, using VHDL and other CAD tools. High-level design is performed.] QuickHDL, Renoir (high-level design and VHDL synthesis, e.g., graphical state machine and truth table entry, and conversion to VHDL).

3. **ELE 405 - Digital Computer Design:** Hardware implementation of digital computers. Arithmetic circuits, memory interface, data path, control path, input/output. Synthesis tools. Gate level design, simulation, construction and verification of a simple digital computer.

   [Design, simulation, construction/emulation and test of the digital hardware realizing the instruction set devised in ELE 305. Gate-level design is performed, along with VHDL aids (e.g., for logic synthesis). The same suite of CAD tools is used. The computer will be emulated, debugged and evaluated, using rapid prototyping hardware (FPGA), and logic analyzers.] Design Architect, QuickHDL, Quicksim II, Renoir, Galileo (VHDL-to-logic synthesis tool).

4. **CSC 402 - Compiler Design:** Grammars and languages; lexical analysis, parsing and translation, symbol tables, runtime storage administration, object code generation. Students will construct a compiler for a small programming language.

   [A compiler providing translation from a high-level programming language to the machine instruction set of the student's computer is written and tested.] HP logic analyzer source-code–to–timing mapper.

5. **ELE 437 - Computer Communications:** Computer networks, layering standards, communication fundamentals, error detection and recovery, queuing and delay-thruput trade-offs in networks, multiple-access channels, design issues in wide and local area networks.

   [A simple wireless or wired local area network is designed, incorporating standard network elements such as layering, error detection and recovery, and throughput management.] Design Architect, Quicksim II, QuickHDL, Renoir.

6. **ELE 408 - Computer Systems Laboratory:** Engineering design problems involving modern microprocessor systems, operation of ALUs, data paths, control units, input/output, and memory systems.

   [The hardware and software of the computer are integrated, and the overall system is debugged and evaluated using benchmark programs. The effect of hardware/software design modifications on cost and performance is measured. The different computers of the entire class are hooked together in a simple network; communication amongst them is achieved. The network is evaluated. The emulation hardware and logic analyzers are again used.] All of the above tools.

Other optional or potential components (these are not initially required, to ease the realization of ICED):

- **CSC 412 - Operating Systems:** Presentation of the general concepts underlying operating systems. Topics include process management, concurrency, scheduling, memory management, information management, protection and security, modeling and performance.

  [A simple operating system / monitor is written and tested for the computer.] HP logic analyzer source-code–to–timing mapper.

- **ELE 447 - VLSI Design and Simulation:** Design and simulation of digital integrated circuits. Extensive use of software tools such as Mentor Graphics' IC Station and simulators. Student designs are fabricated and tested.

  [The computer hardware, or parts thereof, are realized again, this time by designing a custom Integrated Circuit (IC). The IC is fabricated via MOSIS.] IC Station, Lsim, etc.

(The complete curriculum is available via the author's web site: `www.ele.uri.edu/~uht`)

Thus, the students are exposed to many industrial CAD tools in the course of their studies, including schematic capture (Design Architect), hardware programming language use (VHDL, via the QuickHDL tools), high-level design (Renoir), and synthesis (Galileo). With the guidance of the professor, students estimate the consequences on the compiler design when designing the hardware in ELE 305 and 405. During compiler construction in CSC 402, in their Senior year, students may discover that they need or want to change the balance between hardware and software, and modify their hardware designs accordingly. The network component is addressed in ELE 437. Lastly, in ELE 408, all of the pieces are put together. Experiments on hardware/software tradeoffs are performed, and the network is tested.

There are potential problems with a multi-term/year project: students may get out of sync due to leaves of absence, part-time study, etc.; a student's partner may drop out; or, a group may fall far behind. In order to handle these situations, a canned design is available to students to restart with at the beginning of each core course, should they desire or need to start fresh. As an example, a pre-designed CPU is available at the beginning of the Senior year compiler design course.

Equipment - The Mentor suite was chosen as the primary CAD tool provider in the department after an exhaustive evaluation and comparison of the major CAD tool vendors. Mentor was the clear favorite, being the most complete and lowest cost of the vendors' offerings. It is also very popular in industry, and may legally be used in research (both undergraduate and graduate), especially that involving industrial participation.

Last year we received an equipment grant from the National Science Foundation for the support of ICED. With the grant, we have purchased 10 Sun Ultra 1's with 128 MB RAM to run the Mentor tools and the emulation hardware. We are also using our old Sun IPC's as X terminals, one IPC connected to each Ultra, to stretch the number of workstation seats further. We also plan to purchase a Sun compute server, for jobs too large for the Ultra's.

Our lab setup will be based on commercially available rapid prototyping emulation hardware units employing Field Programmable Gate Arrays (FPGA's); they are Virtual Computer Corp. EVC1s units, each containing a Xilinx XC4020E FPGA. The programmability of the FPGA's allows for many experiments of different computer designs to be made. FPGA's are being used more and more in industry, both for final products as well as prototyping, so this will give the student valuable exposure to a modern technology, lacking in the old curriculum. Discrete components will be used for the network interface, adding to the "hands-on" experience. Three or four lab stations are being set up, each with its own emulation unit, logic analyzer and Sun Ultra (out of the 10 above). The laboratory environment is more fully described in [10].

3 Summary, Status and Conclusions

For those students desiring hardware and software computer engineering design skills, as well as the underlying theoretical knowledge to create complex, realistic digital systems, the new URI curriculum will offer a unique experience. We believe that our experiences with this ambitious, new approach to undergraduate curriculum should be a valuable model for programs around the world. The ICED curriculum is a novel attempt to bring the problems and opportunities of a long-term project into the undergraduate curriculum, allowing students to engineer complex digital systems from both software and hardware components, and to comprehend the structure of these systems, from networks to gate-level logic in a CPU. Many aspects of computer architecture are investigated, including Instruction Set Architecture, microarchitecture, system architecture, and network architecture. Hardware/software tradeoffs are studied throughout the curriculum.

ICED is becoming a reality; it has been approved, and became official with the Fall 1997 semester. Although only Freshman were required to begin the new curriculum this past Fall, Sophomores and Juniors were switched to the new curriculum at that time. Thus, the first students following ICED will graduate in one year.

The laboratory equipment is largely in place. The Mentor donation was granted two years ago (Fall 1995). Since then we have have used many of the CAD tools with great success in our courses. The new workstations were installed in the Summer of 1997, and were used in ELE 201/202 and 305 in the Fall of 1997. The FPGA cards for the lab stations were bought and installed in January of 1998, and were used in ELE 405 in the Spring term. The logic analyzers have been purchased and set up. The remainder of the lab stations, especially two custom circuit boards holding external memory and I/O, are being designed and built this Summer, in time for the 1998-99 school year.

The first year of ICED was successful in that almost all of the groups finished their computer designs, and correctly simulated them behaviorally. Most of the groups are close to making their computers operational on the FPGA's, having gotten their designs through Xilinx FPGA synthesis. There were some problems, in that only one group was able to get their computer working in the FPGA during the ELE 405 course, and the time spent by the students on the project was excessive. We are addressing these issues by: (1) providing the current Juniors with a special course to catch up next year; (2) giving the next class a gentler introduction to VHDL, simulation and synthesis; and (3) switching some of the ELE 305 (computer architecture) and 405 (computer design) material around; it should be easier for the students to grasp VHDL concepts if the concepts are presented with logic and gate designs having real delays, rather than just with abstract RTL architectural ideas.

Acknowledgments

The new ICED curriculum is the result of many peoples' efforts over many years. An initial version was proposed with Laurette Bradley at UCSD in 1987-88. Independently, J.C. Lo began work on something similar at URI in the early '90's. The main effort in realizing the final ICED curriculum comes from the faculty of the Electrical and Computer Engineering Department at URI, especially: G. Sadasiv, J. Daly, G. Fischer, J.-C. Lo, W. Ohley, Y. Sun, D. Tufts, and Q. Yang. J. Kowalski of Computer Science is heading the compiler part of the project. Our systems staff people, especially T. Toolan and T. Nightingale, have been critical in making it happen. We have also been aided by Glenn Erickson and Bette Erickson of the URI Instructional Development Program.
